

Use html syntax

First modify the _config.yml file

Set the post_asset_folder option in _config.yml to true

1	post_asset_folder: true
---	-------------------------

The function description of this option is as follows:

When you set the post_asset_folder parameter to true, when the file is created, Hexo
A folder with the same name as the article will be automatically created, and you can put all the
resources related to the article in that folder. In this way, you can use the resources more
conveniently.

Then create a new article

1	\$ hexo new
---	-------------

Since the post_asset_folder option has been set to true in the previous step
So when creating a new article in this step, an md file and a folder with the same name will be
created
For convenience of description, I use test as the file and folder name

Edit test.md

Open test.md with vim or another editor

Add the following code to the test.md file

```
<object      data="./test/test.pdf"      type="application/pdf"      width="100%"  
height="100%">
```

A simple explanation of this code

data represents the path of the pdf you want to upload, using a relative path, put the pdf you want to upload into the test folder generated in the second step

I won't talk about type and width. Note that the height cannot be set to 100%, otherwise it's too

short and the display effect is not good.

You can use the browser to preview and estimate the height through F12. My final code is as follows, for reference

```
<object  
data="http://image.fiftykg.com/pdf/%E5%BE%AE%E4%BF%A1%E5%85%AC%E4%BC%97%E5%8F%B7  
" type="application/pdf" width="100%" height="877px">
```

The object tag is not necessarily used here, the same is true for embed and iframe tags

Specific reference:Web links

note:

Using the html method, in my theme, if there is text behind it, it will not be displayed for unknown reasons. So the example I showed at the bottom of the article
